## Summary

Cable-stayed bridges are structural systems effectively composing cables, main girders and towers. This bridge form has a beautiful appearance and easily fits in with the surrounding environment due to the fact that various structural systems can be created by changing the tower shapes and cable arrangements.

To determine the cable prestress forces that are introduced at the time of cable installation, the initial equilibrium state for dead load at the final stage must be determined first. Then, construction stage analysis according to the construction sequence is performed.

In general, with forward construction stage analysis, we cannot obtain cable pretension loads for each stage which satisfy the initial equilibrium state at the final stage. By using cable pretension loads resulting from backward stage analysis, we can perform forward stage analysis. However, newly added function, Lack-of-Fit Force finds cable pretension loads for each construction stage from cable pretension loads at the final stage without backward stage analysis.

This tutorial explains techniques for modeling a cable-stayed bridge, calculating initial cable prestress forces, performing construction stage analysis and reviewing the output data. The model used in this tutorial is a three span continuous cable-stayed bridge composed of a 110 m center span and 40 m side spans. Fig. 1 below shows the bridge layout.

*Fig. 1 Cable-stayed bridge analytical model*

## Bridge Dimensions

The bridge model used in this tutorial is simplified because its purpose is to explain the analytical sequences, and so its dimensions may differ from those of a real structure.

The dimensions and loadings for the three span continuous cable-stayed bridge are as follows:

Bridge type	Three span continuous cable-stayed bridge
Bridge length	$L = 40\text{ m} + 110\text{ m} + 40\text{ m} = 190\text{ m}$
Bridge Height	Lower part of tower: 20 m, Upper part of tower: 40 m

*Fig. 2 General layout*

## Loading

Classification	Loading Type	Loading Value
Dead Load	Self weight	Automatically calculated within the program
Cable Prestress Force	Pretension Load	Cable prestress forces that satisfy initial equilibrium state at the final stage
Derrick Crane	Nodal Load	80 tonf
Jack Up Load	Specified Displacement	10 cm

We input the initial cable prestress force values, which can be calculated by the built-in optimization technique in MIDAS/Civil.

## Working Condition Setting

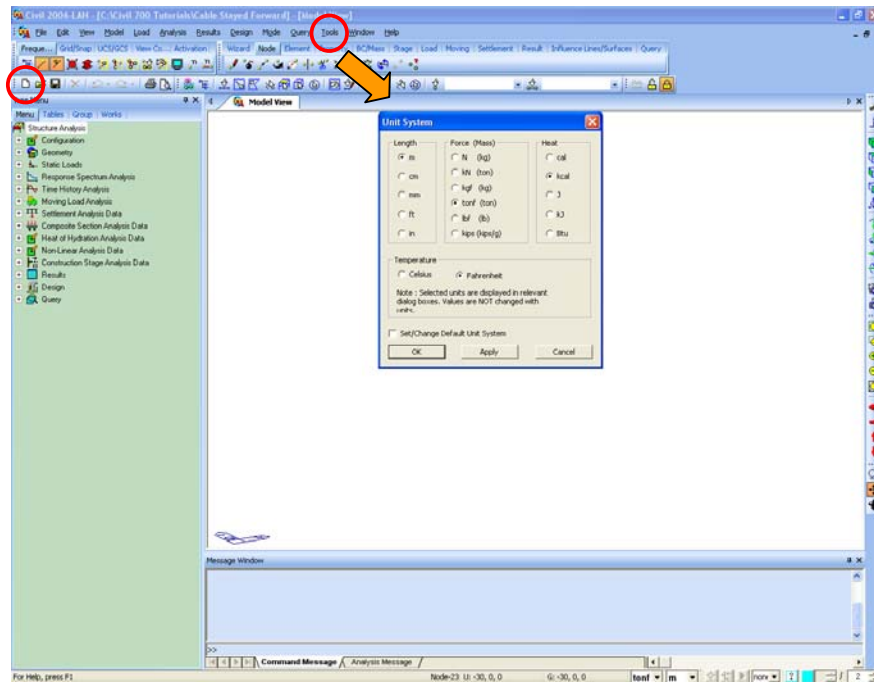

To perform the final stage analysis for the cable-stayed bridge, open a new file and save it as '**Cable Stayed Forward**', and start modeling. Assign '**m**' for length unit and '**tonf**' for force unit. This unit system can be changed any time during the modeling process for user's convenience.

File /  **New Project**

File /  **Save (Cable Stayed Forward)**

Tools / **Unit System**

## Definition of Material and Section Properties

Input material properties for the main girders, tower-bottom, tower-top and cables. Click **Add** button under Material tab in Properties dialog box.

Model / Properties /  **Material**

Name (**Girder**); Type of Design>**User Defined**

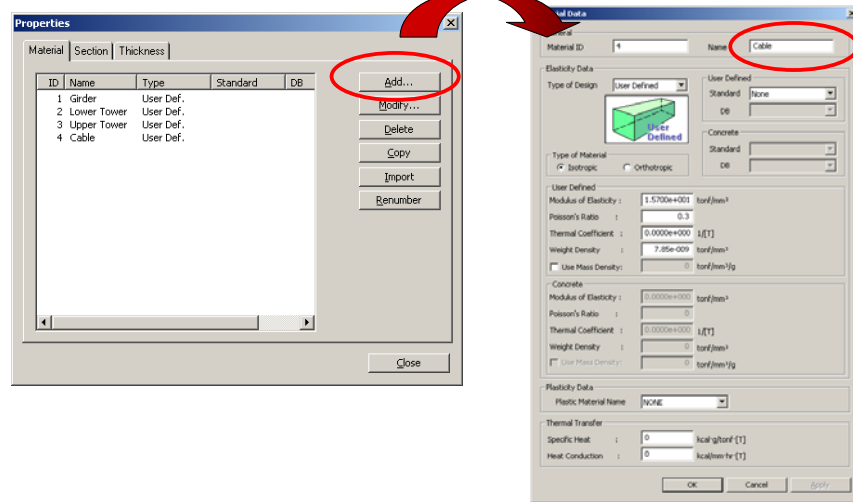

Modulus of Elasticity (**2.1e7**); Poisson's Ratio (**0.3**)

Weight Density (**7.85**) ↵

Input material properties for the tower-bottom, tower-top and cables similarly. The input values are shown in Table 1.

**Table 1 Material Properties**

ID	Component	Modulus of Elasticity (tonf/m <sup>2</sup> )	Poisson's Ratio	Weight Density (tonf/m <sup>3</sup> )
1	Girder	$2.1 \times 10^7$	0.3	7.85
2	Lower Tower	$2.5 \times 10^6$	0.17	2.5
3	Upper Tower	$2.1 \times 10^7$	0.3	7.85
4	Cable	$1.57 \times 10^7$	0.3	7.85

**Fig. 4 Defined Material Properties**

Input section properties for the girders, tower-bottom, tower-top and cables. Click **Add** button under Section tab in Properties dialog box.

Model / Properties /  **Section**

**Value tab**

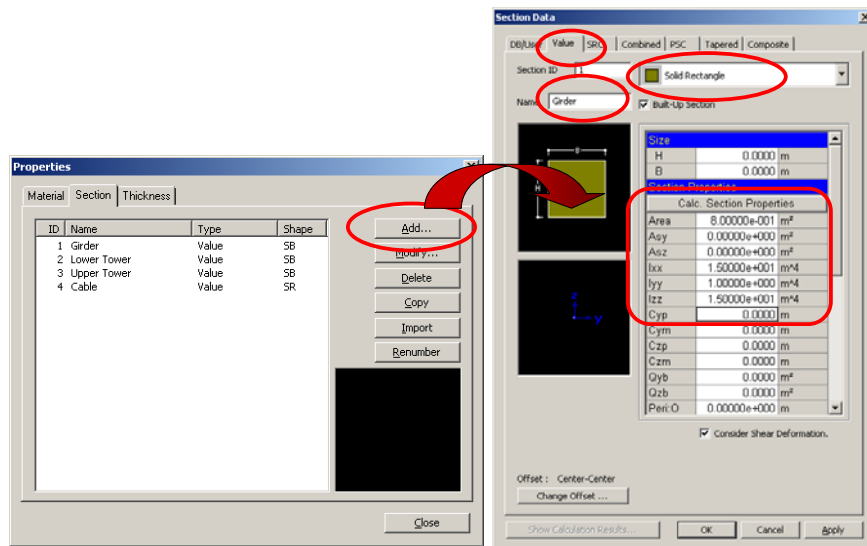

Section ID **(1)**; Name **(Girder)**

Section Shape>**Solid Rectangle**; Stiffness>Area **(0.8)** ↵

Input section properties for the tower-bottom, tower-top and cables similarly. The values are shown in Table 2.

**Table 2 Section Properties**

ID	Component	Area (m <sup>2</sup> )	Ixx (m <sup>4</sup> )	Iyy (m <sup>4</sup> )	Izz (m <sup>4</sup> )
1	Girder	0.8	15.0	1.0	15.0
2	Lower Tower	50.0	1000.0	500.0	500.0
3	Upper Tower	0.3	5.0	5.0	5.0
4	Cable	0.005	0.0	0.0	0.0

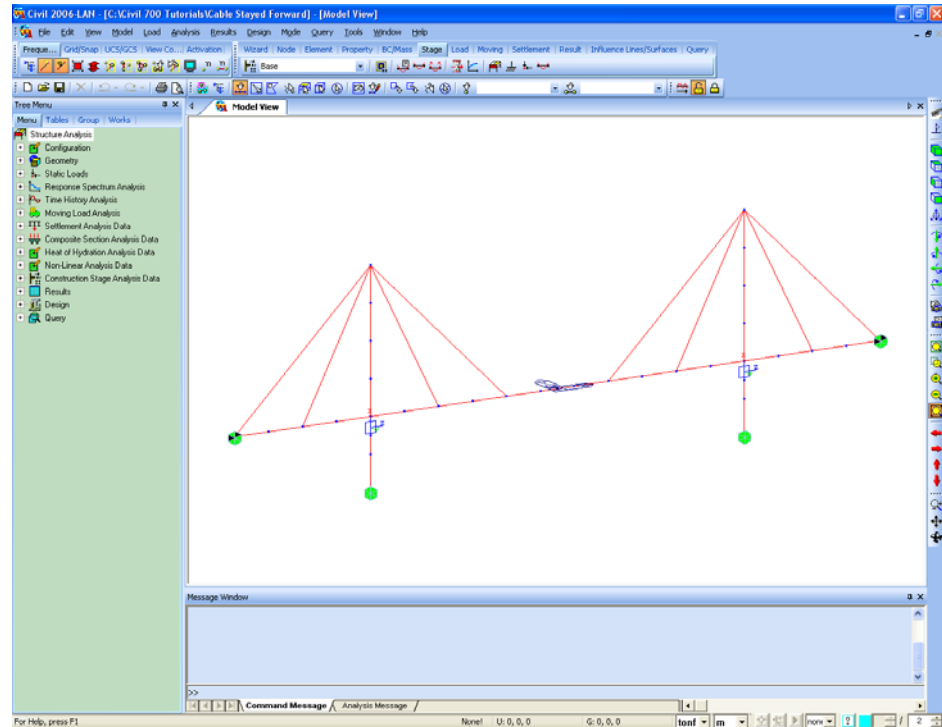

**Fig. 5 Defined Section Properties**

## Final Stage Analysis

After completion of the final stage modeling for the cable-stayed bridge, we calculate the cable initial prestress forces for self-weights and additional dead loads. After that, we perform initial equilibrium state analysis with the calculated initial prestress forces.

To perform structural modeling of the cable-stayed bridge, we first generate a 2D model by Cable Stayed Bridge Wizard provided in **MIDAS/Civil**. Initial cable forces introduced in the final stage can easily be calculated by the Unknown Load Factors function, which is based on an optimization technique. The final model of the cable-stayed bridge is shown in Fig. 6.

*Fig. 6 Final Model for Cable-Stayed Bridge*

## Bridge Modeling

In this tutorial, the analytical model for the final stage analysis will be completed first and subsequently analyzed. The final stage model will then be saved under a different name, and then using this model the construction stage model will be developed.

Modeling process for the final stage analysis of the cable-stayed bridge is as follows:

- 
1. Main Girder Modeling
  2. Tower Modeling
  3. Cable Modeling
  4. Tower Bearing Generation
  5. Boundary Condition Input
  6. Initial cable Prestress Force Calculation by Unknown Load Factors
  7. Loading Condition and Loading Input
  8. Perform Structural Analysis
  9. Unknown Load Factors Calculation
-

## Main Girder Modeling

First generate nodes, and then model the girder (9@10+2@5+9@10m) by using the Extrude Element function.

 **Front View**,  **Node Snap** (on),  **Element Snap** (on)

 **Auto Fitting** (on),  **Node Number** (on)

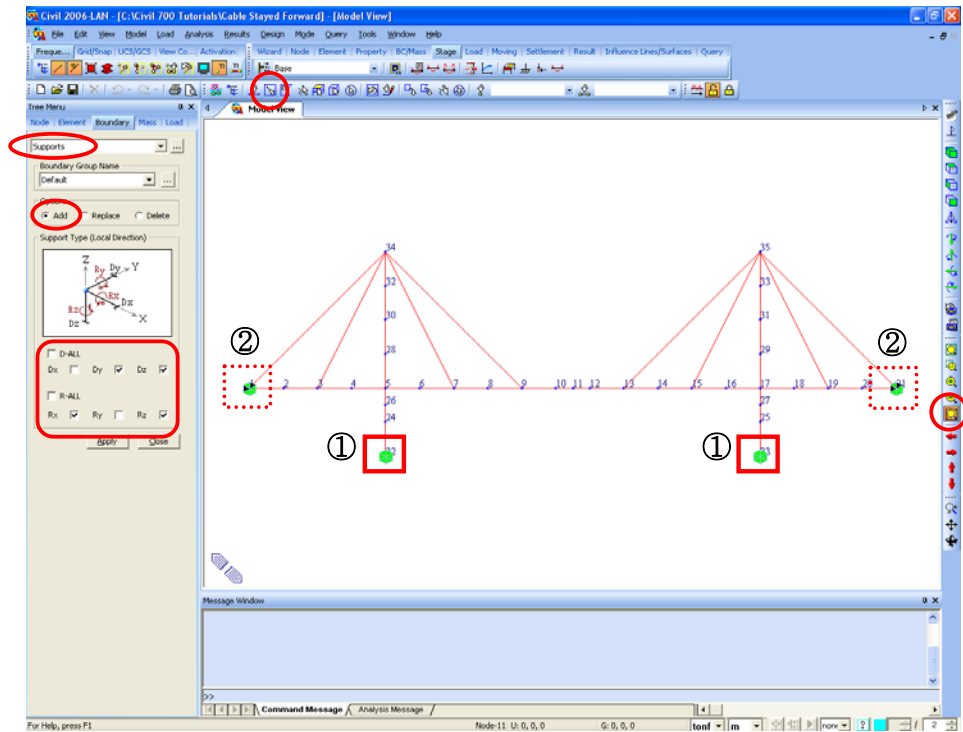

Fig. 12 Specifying Fixed Boundary Conditions for Tower and Pier Bases

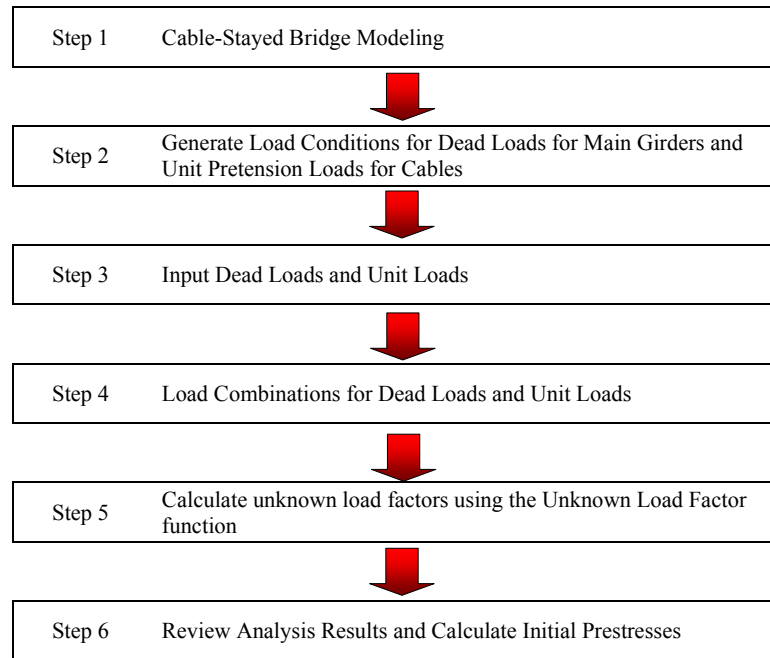

## Cable Initial Prestress Calculation

The initial cable prestress, which is balanced with dead loads, is introduced to improve section forces in the main girders and towers, cable tensions and support reactions in the bridge. It requires many iterative calculations to obtain initial cable prestress forces because a cable-stayed bridge is a highly indeterminate structure. And there are no unique solutions for calculating cable prestresses directly. Each designer may select different initial prestresses for an identical cable-stayed bridge.

The **Unknown Load Factor** function in **MIDAS/Civil** is based on an optimization technique, and it is used to calculate optimum load factors that satisfy specific boundary conditions for a structure. It can be used effectively for the calculation of initial cable prestresses.

The procedure of calculating initial prestresses for cable-stayed bridges by Unknown Load Factor is outlined in Table 3.

*Table 3. Flowchart for Cable Initial Prestress Calculation*

## Loading Condition Input

Input loading conditions for self-weight, superimposed dead load and unit loads for cables to calculate initial prestresses for the dead load condition. The number of required unknown initial cable prestress values will be set at 4, as the bridge is a symmetric cable-stayed bridge, which has 4 cables on each side of each tower. Input loading conditions for each of the 4 cables.

It may be more convenient to use the MCT Command Shell for the input of loading conditions.

### Load / Static Load Cases

Name **(Self Weight)**; Type>**Dead Load**

## Unknown Load Factors Calculation

Calculate unknown load factors that satisfy the boundary conditions by the *Unknown Load Factor* function for LCB1, which was generated through load combination. The constraints are specified to limit the horizontal deflection (Dx) of the tower and the bending moment (My) of the girders.

Specify the load condition, constraints and method of forming the object function in *Unknown Load Factor*. First, we define the cable unit loading conditions as unknown loads.

### Results / *Unknown Load Factor*

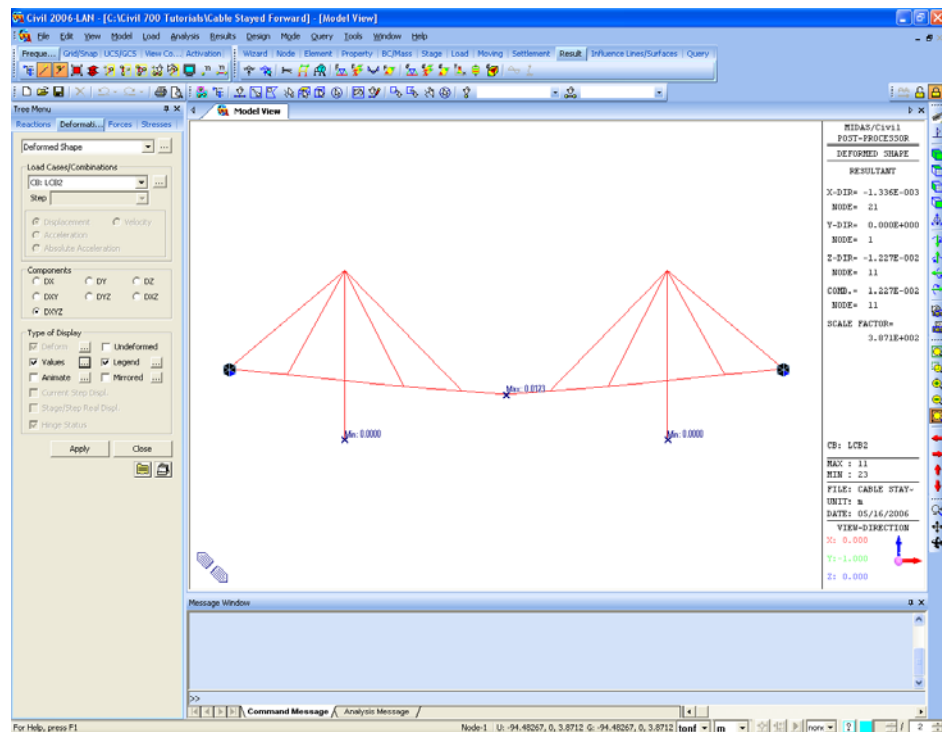

Fig. 30 Check Deformed Shape

## Forward Construction Stage Analysis

When a cable stayed bridge is designed, the structural configuration, cable sections and tension forces are generally calculated from the overall analysis of the completed state.

Apart from the analysis for the completed state, construction stage analysis is also required for design of the cable stayed bridge. Depending on the temporary support method, the structural system of a cable stayed bridge changes drastically during construction. The structural system may become unsafe and/or unstable during the construction compared to the completed state. This necessitates a construction stage analysis, and the analysis based on the construction sequence is referred to as Forward Analysis. Stresses, deflection, sequence, constructability, etc. can be checked through Forward Analysis. One of the difficulties associated with forward stage analysis is to find tension forces at construction stages. With the facility of the lack of fit force functionality, additional pretension loads, which are introduced during the installation of cables, are calculated, and member forces are preloaded at Key Segment such that member forces at key segment closure are the same as those at the completed state. Using these pretension and member forces, forward stage analyses are performed.

To perform a construction stage analysis, construction stages should be defined to consider the effects of the activation and deactivation of main girders, cables, cable anchorage, boundary conditions, loads, etc. Each stage must be defined to represent a meaningful structural system, which changes during construction.

*Fig. 31 Construction Sequence and Analysis Sequence for a Cable Stayed Bridge*

**(1) Calculating Lack of Fit Force - Truss**

First, displacements at each end of cables are calculated at a stage immediately before the cables are installed. Using the displacements at each cable end, the program calculates the additional cable pretension ( $\Delta T$ ), the difference between the cable length ( $L$ ) at the completed state and the cable length ( $L'$ ) during the construction. This additional cable pretension ( $\Delta T$ ) is added to the initial Pretension ( $T$ ) determined from the initial configuration analysis; that is, it is entered as Pretension during the construction to perform forward analysis.

$$L' - L = \Delta L = v_b \cos \theta + u_b \sin \theta$$

$$\Delta T = \frac{EA}{L} \Delta L$$

$$T_f = T_i + \Delta T$$

**Fig. 32 Calculating Lack of Fit Force of Truss**

## (2) Calculating Lack of Fit Force – Beam

At the time of key segment closure for a 3-span continuous cable stayed bridge, cantilevers of the center span are deflected. If the key segment is closed in this state, no member force takes place at the key segment (only member forces due to self-weight take place) and there is discontinuity between the cantilevers and the key segment. To connect the key segment to each cantilever member continuously, Lack-of-Fit Force function calculates specified displacements required at each end of the key segment and converts the specified displacements into member forces to apply these forces to the key segment.

*Fig. 33 Calculating Lack of Fit Force of Beam*

## Construction Stage Category

In this tutorial, 13 construction stages are generated to simulate the changes of loading and boundary conditions.

Forward analysis is performed using Cable Pretension obtained from the initial equilibrium state analysis. Lack-of-Fit Force function is applied to cables, key segment in the center span and side span girders activated at Stage 2. We apply Lack-of-Fit Force function to a side span girder erection stage where girders are connected to the supports and accordingly structural system changes, not to mention the key segment closure in the center span.

The construction stages applied in this tutorial are outlined in Table 5.

**Table 5 Construction Stage Category**

Stage	Content	Remark
Stage 1	Install towers, end supports in the side spans, temporary bents, and temporary connection between tower-girder	
Stage 2	Install side spans (Elements 1 to 5 & 16 to 20)	Lack-of-Fit Force
Stage 3	Apply Derrick Crane1 load	
Stage 4	Remove temporary bents and generate cables (Element 34, 39)	Lack-of-Fit Force
Stage 5	Generate main girders (Element 6, 7, 14, 15)	
Stage 6	Generate cables (Element 35, 38)	Lack-of-Fit Force
Stage 7	Remove Derrick Crane1 load and apply Derrick Crane2 load	
Stage 7-1	Generate cables (Element 33, 40)	Lack-of-Fit Force
Stage 8	Generate main girders (Element 8, 9, 12, 13)	
Stage 9	Generate cables (Element 36, 37)	Lack-of-Fit Force
Stage 10	Remove Derrick Crane2 load and apply Derrick Crane3 load	
Stage 11	Remove Derrick Crane3 load	
Stage 11-1	Generate KEY SEG (Element 10, 11)	Lack-of-Fit Force
Stage 12	Replace the connection between tower-girder and apply Jack Up load	Rigid link→ Elastic link
Stage 13	Apply additional dead loads (Final Stage)	

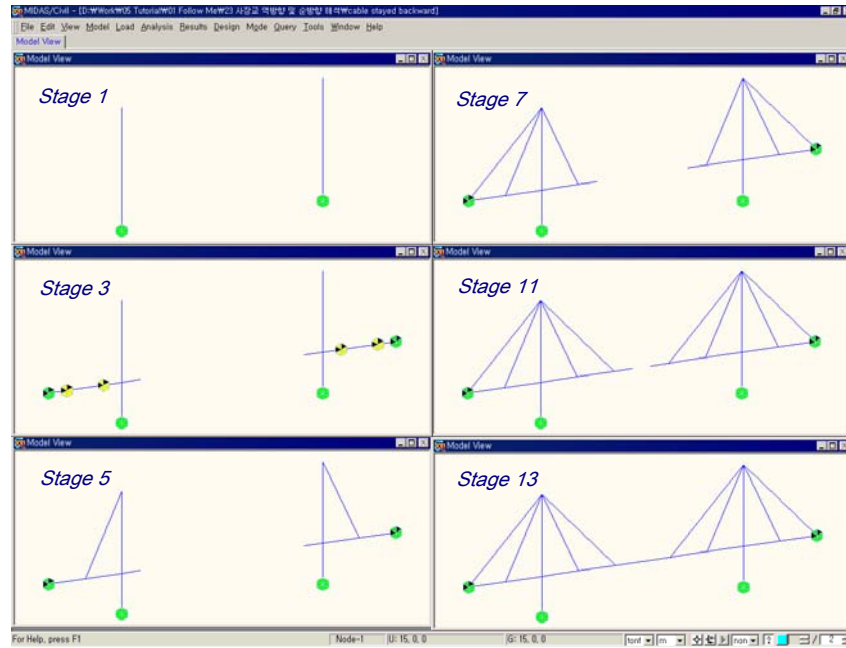

## Forward Construction Stage Analysis

Forward analysis reflects the real construction sequence.

In this tutorial, we will examine the structural behavior of the analytical model and the changes of cable tensions, displacements and moments.

The analytical sequence of forward construction stage analysis is as shown in Fig. 34.

*Fig. 34 Analysis Sequence by Forward Construction Stage Analysis*

We will generate a construction stage analytical model using the model used in the final stage analysis by saving the file under a different name.

---

File / *Save As* (**Cable Stayed Forward Construction**)

---

The following steps are carried out to generate the construction stage analysis model:

- 
1. **Save a forward stage analytical model**  
Change the truss element used in the final stage analysis to cable element.  
Define load cases for forward analysis.
  2. **Define Construction Stage names**  
Define each construction stage and the name.
  3. **Define Structural Group**  
Define the elements by group, which are added/deleted in each stage and to which Lack-of-Fit Force is applied.
  4. **Define Boundary Group**  
Define the boundary conditions by group, which are added/deleted in each stage.
  5. **Define Load Group**  
Define the loading conditions by group, which are added/deleted in each stage.
  6. **Define Construction Stages**  
Define the elements, boundary conditions and loadings pertaining to each stage.
-

## Save a Forward Stage Analytical Model

In order to create the construction stage analysis model from the final stage model, delete the load combinations LCB 1 & 2 and unit pretension loading conditions, Tension 1 to Tension 4. To input Pretension Loads calculated by forward stage analysis, define a new loading case for Cable Pretension.

Results / *Combinations*

Load Combination List>Name>**LCB 1, LCB 2**

*Fig. 35 Entering Initial Prestress Loading Condition*

In construction stage analysis for cable-stayed bridges, geometrical nonlinear analysis for cable element should be performed. To consider the sag effect of cable element in cable-stayed bridges, the truss elements used in the final stage analysis should be transformed to cable elements. In a cable-stayed bridge, an equivalent truss element is used for the cable element. This element considers the stiffness due to tensioning.

## Define Construction Stage

We now define each construction stage to perform forward construction stage analysis. First, we assign each construction stage name in the Construction Stage dialog box. In this tutorial, we will define total 13 construction stages including the final stage.

Define multiple construction stages simultaneously by assigning numbers to a particular name.

For generating analysis results, the analysis results in each construction stage are saved and subsequently generated.

## Assign Structure Group

Assign the elements, which are added/deleted in each construction stage by Structure Group. After defining the name of each Structure Group, we then assign relevant elements to the Structure Group.

Group tab

☐ Group>Structure Group>New...  
 Name **(Stage)**; Suffix **(1to13)**   
 Name **(Lack of Fit Force)**

**Fig. 42 Defining Structure Group**

Assign the elements, which become added/deleted in each construction stage, to each corresponding Structure Group. The tower erection stage is defined as the Stage 1 Structure Group. We skip Stage 3 and Stage 10 because they are construction stages, in which Derrick Crane load at the center span is applied, and as such there are no added/deleted elements involved.

## Assign Load Group

Assign the loading conditions, which become added / deleted in each construction stage, to each corresponding Load Group. The loads considered in this forward construction stage analysis are self-weight, superimposed dead load, cable pretension 1, 2, 3, 4, Jack Up load and Derrick Crane load 1, 2, 3. First, we generate the name of each Load Group and then assign corresponding loading conditions to each Load Group.

Load Group	Element No.	Pretension Loading	Load Group	Element No.	Pretension Loading
Pretension Load 1	36, 37	340.835	Pretension Load 3	35, 38	193.011
Pretension Load 2	33, 40	333.808	Pretension Load 4	34, 39	254.370

## Assign Construction Stage

We now assign the predefined Structure Group, Boundary Group and Load Group to each corresponding construction stage. First, we assign Stage 1 to Construction Stage as the 1<sup>st</sup> stage in forward analysis. Stage 1 is a construction stage, which installs towers.

 Cable-Pretension Force Control > **Internal Force** (on)  
 Initial Tangent Displacement Erected Structures> **All** (on)  
 Lack of Fit Force Control (on) > **Lack of Fit Force** (Select) ↵

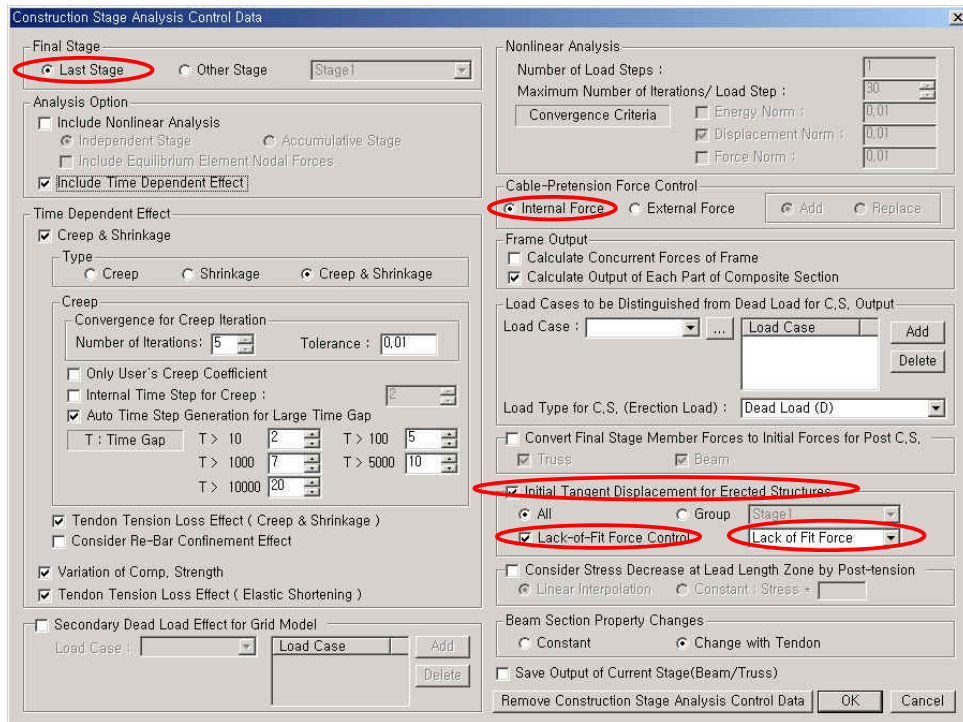

Fig. 65 Construction Stage Analysis Control Data Dialog Box

### Adjusting Cable-Pretension using Cable-Pretension Force Control and Lack of Fit Force Control

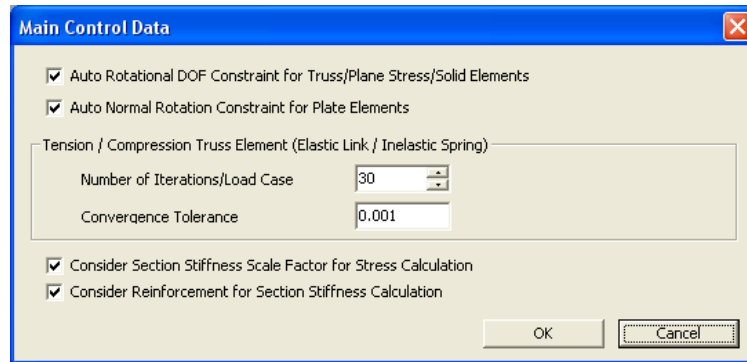

Cable-Pretension Force Control function is used to control Cable-Pretension for construction stage analysis of a cable stayed bridge. In general, due to force redistribution we cannot expect the resultant cable forces whose magnitude is the same as the Pretension Loads entered. External Force type is selected when the user directly enters cable pretension. In this tutorial, since we use pretension obtained from the completed state, we select Internal Force type and Lack-of-Fit Force Control to automatically calculate pretension for each stage.

## Main Control Data

For convergence, we change the default for Number of Iterations/Load Case (20) to 30.

Tension / Compression Truss Element (Elastic Link / Inelastic Spring)

Number of Iterations/Load Case > **30**

## Perform Structural Analysis

Perform construction stage analysis for self-weight, superimposed dead load, Jack Up load and Derrick Crane load.

Analysis /  **Perform Analysis** ↵

## Review Construction Stage Analysis Results

Review the changes of deformed shapes and section forces for each construction stage by construction stage analysis.

### Review Deformed Shapes

Review the deformed shape of the main girders and towers for each construction stage.

If the Stage Toolbar is active, the analysis results can be easily monitored in the Model View by selecting construction stages using the arrow keys on the keyboard.

Stage Tab > Stage Toolbar > **Stage 6**

Result / Deformations / **Deformed Shape**

Load Cases/Combinations > **CS:Dead Load**

Components > **DXYZ**; Type of Display > **Undeformed** (on); **Legend** (on)

Deform > Deformation Scale Factor (**0.5**)

Values > Value Output Details

Decimal Points > (**4**) ; **MinMax Only** (on) ; **Min & Max** (on)

Stage/Step Real Displ. (on)

If the default Deformation Scale Factor is too large, we can adjust the Scale Factor.

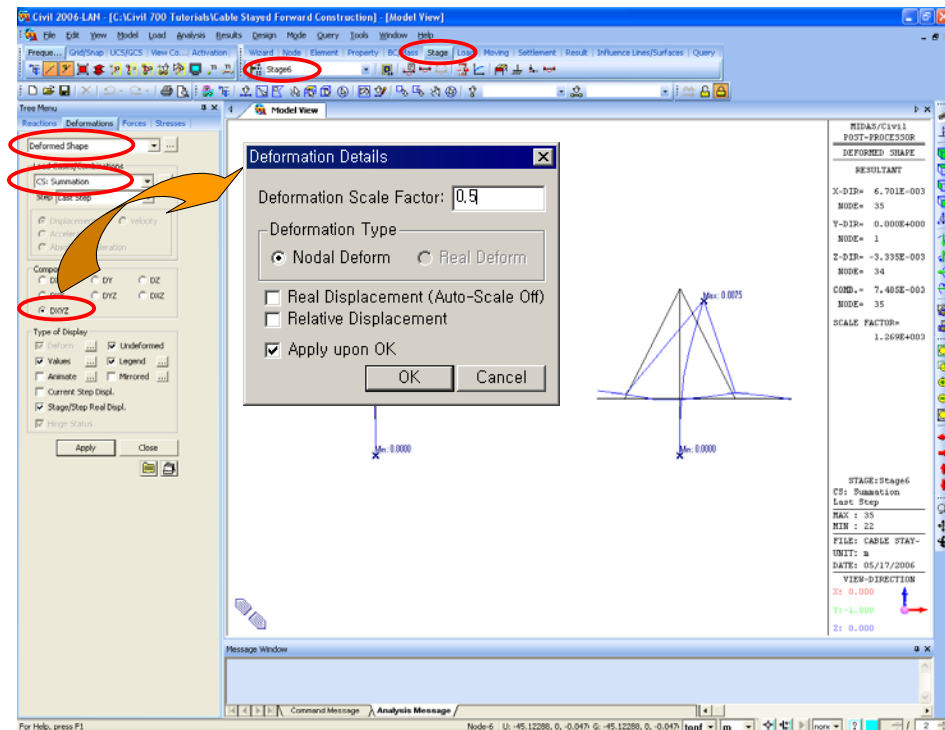

Fig. 66 Deformed Shape for Each Construction Stage from Forward Analysis

## Review Bending Moments

For each construction stage, we review bending moments for the main girders and towers.

Result / Forces /  **Beam Diagrams**

Load Cases>Combinations>**CS:Summation**

Components>**My**

Display Options>**5Points**; **Solid Fill**
